## Aggregate results in WHERE

The right way

Account			
Number	Branch	CustID	Balance
111	London	1	1330.00
222	London	2	1756.00
333	Edinburgh	1	450.00

Accounts with a **higher balance** than the **average of all accounts**

```
SELECT A.number
FROM Account A
WHERE A.balance > ( SELECT AVG(A1.balance)
                   FROM Account A1 );
```

Answer:

Number
111
222

## Aggregate results in WHERE

The wrong way

Accounts with a higher balance than the average of all accounts

```
SELECT  A.number
FROM    Account A
WHERE   A.balance > AVG( SELECT A1.balance
                        FROM   Account A1 );
```

### ERROR

Aggregate functions can only be used in **SELECT** and **HAVING**

## Comparisons with subquery results

```
SELECT ...
FROM    ...
WHERE   term op ( subquery ) ;
```

Allowed as long as **subquery** returns a **single value**

```
SELECT ...
FROM    ...
WHERE   (term1, ..., termn) op ( subquery ) ;
```

Allowed as long as **subquery** returns a **single row** with  $n$  columns

# The WHERE clause revisited

term := attribute | value

comparison :=

- ▶ (term, ..., term) **op** (term, ..., term)  
with **op** ∈ {=, <>, <, >, <=, >=}
- ▶ term **IS** [**NOT**] **NULL**
- ▶ (term, ..., term) **op ANY** ( query )
- ▶ (term, ..., term) **op ALL** ( query )
- ▶ (term, ..., term) [**NOT**] **IN** ( query )
- ▶ **EXISTS** ( query )

condition :=

- ▶ condition1 **AND** condition2
- ▶ condition1 **OR** condition2
- ▶ **NOT** condition

## Comparisons between tuples

$$(A_1, \dots, A_n) = (B_1, \dots, B_n) \iff A_1 = B_1 \wedge \dots \wedge A_n = B_n$$

$$(A_1, \dots, A_n) <> (B_1, \dots, B_n) \iff A_1 \neq B_1 \vee \dots \vee A_n \neq B_n$$

$$(A_1, A_2, A_3) < (B_1, B_2, B_3) \quad \text{(generalizes to } n \text{ elements)}$$

$$\iff A_1 < B_1 \vee \left( A_1 = B_1 \wedge \left( A_2 < B_2 \vee (A_2 = B_2 \wedge A_3 < B_3) \right) \right)$$

$$(A_1, A_2, A_3) <= (B_1, B_2, B_3) \quad \text{(generalizes to } n \text{ elements)}$$

$$\iff A_1 < B_1 \vee \left( A_1 = B_1 \wedge \left( A_2 < B_2 \vee (A_2 = B_2 \wedge A_3 \leq B_3) \right) \right)$$

## ANY

$(\text{term}, \dots, \text{term}) \text{ op ANY ( query )}$

True if **there exists** a row  $\bar{r}$  in the results of *query* such that  $(\text{term}, \dots, \text{term}) \text{ op } \bar{r}$  is true

### Examples:

- ▶  $3 < \text{ANY}(\{1, 2, 3\})$  is false
- ▶  $3 < \text{ANY}(\{2, 3, 4\})$  is true
- ▶ What about  $3 < \text{ANY}(\{\})$  ?

## ALL

$(\text{term}, \dots, \text{term}) \text{ op ALL ( query )}$

True if **for all** rows  $\bar{r}$  in the results of *query*  $(\text{term}, \dots, \text{term}) \text{ op } \bar{r}$  is true

### Examples:

- ▶  $3 < \text{ALL}(\{5, 4, 6\})$  is true
- ▶  $3 < \text{ALL}(\{4, 3, 5\})$  is false
- ▶ What about  $3 < \text{ALL}(\{\})$  ?

## Examples with ANY / ALL

Customer: *ID, Name, City*

Account: *Number, Branch, CustID, Balance*

ID of customers from London who own an account

```
SELECT C.id
FROM    customer C
WHERE    C.city = 'London'
          AND C.id = ANY ( SELECT A.custid
                           FROM    Account A );
```

Customers living in cities without a branch

```
SELECT *
FROM    customer C
WHERE    C.city <> ALL ( SELECT A.branch
                        FROM    Account A );
```

## IN / NOT IN

(term, ..., term) **IN** ( query )

same as

(term, ..., term) = **ANY** ( query )

(term, ..., term) **NOT IN** ( query )

same as

(term, ..., term) <> **ALL** ( query )

## Examples with IN / NOT IN

ID of customers from London who own an account

```
SELECT C.id
FROM   customer C
WHERE  C.city = 'London'
      AND C.id IN ( SELECT A.custid
                    FROM   Account A );
```

Customers living in cities without a branch

```
SELECT *
FROM   customer C
WHERE  C.city NOT IN ( SELECT A.branch
                      FROM   Account A );
```

## EXISTS

**EXISTS** ( query ) is true if the result of query is **non-empty**

### (Stupid) Example

Return all the customers if there are some accounts in London

```
SELECT *
FROM   Customer
WHERE  EXISTS ( SELECT 1
                FROM   Account
                WHERE  branch='London' );
```

## Correlated subqueries

All nested queries can refer to attributes in the **parent queries**

### (Smarter) Example

Return customers who have an account in London

```
SELECT *
FROM Customer C
WHERE EXISTS ( SELECT 1
                FROM Account A
                WHERE branch='London'
                AND A.custid = C.id );
```

**parameters** = attributes of a subquery that refer to outer queries

## Examples with EXISTS / NOT EXISTS

ID of customers from London who own an account

```
SELECT C.id
FROM customer C
WHERE C.city = 'London'
AND EXISTS ( SELECT *
              FROM Account A
              WHERE A.custid = C.id);
```

Customers living in cities without a branch

```
SELECT *
FROM customer C
WHERE NOT EXISTS ( SELECT *
                   FROM Account A
                   WHERE A.branch = C.city );
```

# Scoping

A subquery has

- ▶ a **local scope** (its **FROM** clause)
- ▶  $n$  **outer scopes** (where  $n$  is the **level of nesting**)  
(these are the **FROM** clauses of the parent queries)

For each **reference** to an attribute

1. Look for a binding in the local scope
2. If no binding is found, look in the **closest** outer scope
3. If no binding is found, look in the next closest outer scope
4. ...
5. If no binding is found, give error

## Attribute bindings

```
SELECT *  
FROM table1  
WHERE EXISTS ( SELECT 1  
                FROM table2  
                WHERE A = B );
```

What  $A$ ,  $B$  refer to depends on the attributes in **table1** and **table2**

- ▶ Always give aliases to tables
- ▶ Always prefix the attributes with the tables they refer to

```
SELECT *  
FROM table1 T1  
WHERE EXISTS ( SELECT 1  
                FROM table2 T2  
                WHERE T2.A = T1.B );
```

# The FROM clause revisited

**FROM** table<sub>1</sub> [[**AS**] *T*<sub>1</sub>], ..., table<sub>*n*</sub> [[**AS**] *T*<sub>*n*</sub>]

table :=

- ▶ base-table
- ▶ join-table
- ▶ ( query )

join-table :=

- ▶ table **JOIN** table **ON** condition
- ▶ table **NATURAL JOIN** table
- ▶ table **CROSS JOIN** table

## Subqueries in FROM

Must always be given a name

```
SELECT * FROM ( SELECT * FROM R );
```

ERROR: subquery in FROM must have an alias

Cannot refer to attributes of other tables in the same **FROM** clause

```
SELECT *  
FROM R, ( SELECT * FROM S WHERE S.a=R.a ) S1 ;
```

ERROR: invalid reference to FROM-clause entry for table "r"

## Example: Avoiding HAVING

Branches with a total balance (across accounts) of at least 500

```
SELECT    A.branch
FROM      Account A
GROUP BY  A.branch
HAVING    SUM(A.balance) >= 500 ;
```

Same query without **HAVING**:

```
SELECT subquery.branch
FROM   ( SELECT    A.branch, SUM(A.balance) AS total
        FROM      Account A
        GROUP BY  A.branch ) AS subquery
WHERE  subquery.total >= 500 ;
```

## Example: Aggregation on aggregates

**Average of the total** balances across each customer's accounts

1. Find the total balance across each customer's accounts
2. Take the average of the totals

```
SELECT    AVG(subquery.tot)
FROM      ( SELECT    A.custid, SUM(A.balance) AS tot
        FROM      Account A
        GROUP BY  A.custid ) AS subquery ;
```
